

How does a

hurricane

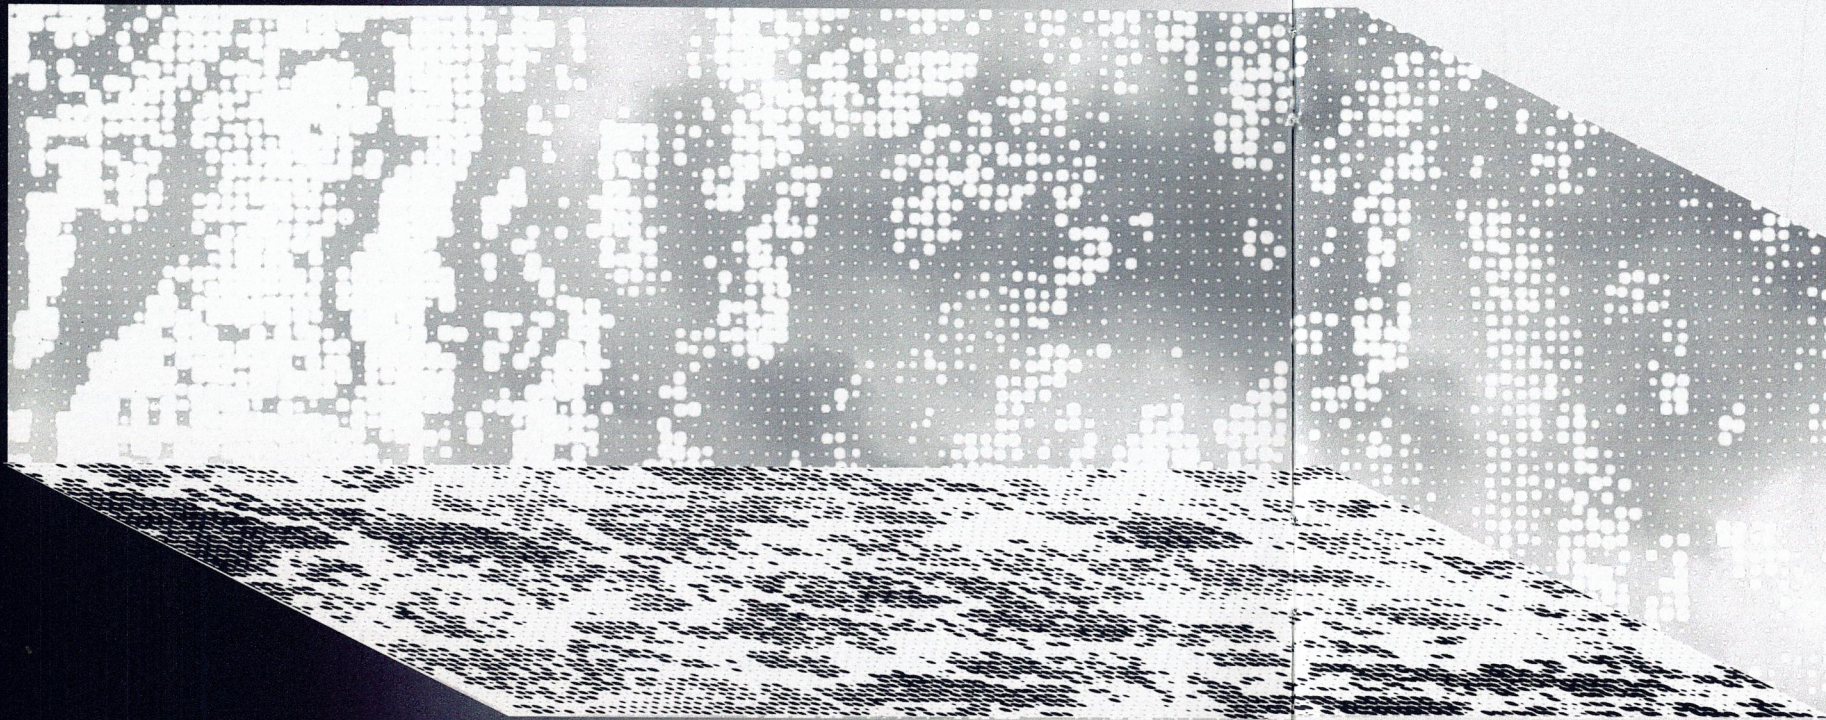

form ?

Project 1: Tell Me How (image + text version)

Hurricanes are like

giant
engines

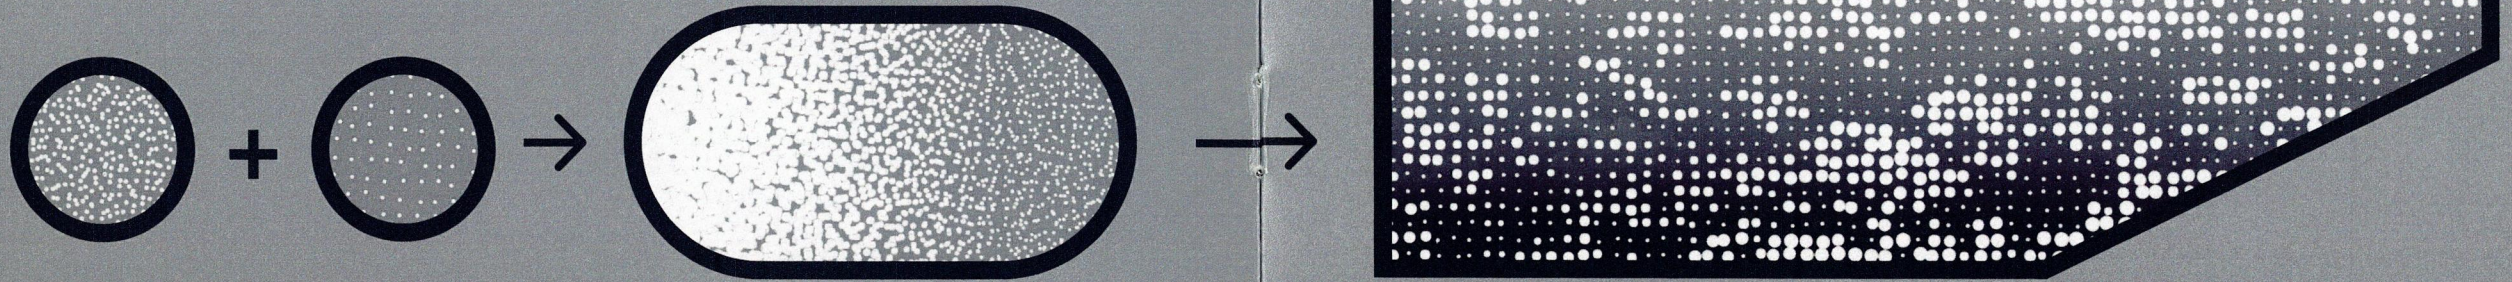

that uses

warm, moist
air

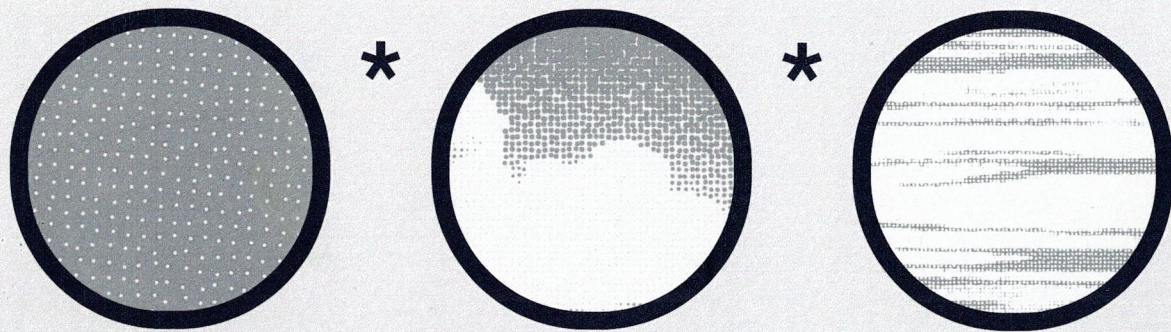

as fuel.

The air over the ocean rises upward leaving less air near the surface. This creates an area of lower pressure.

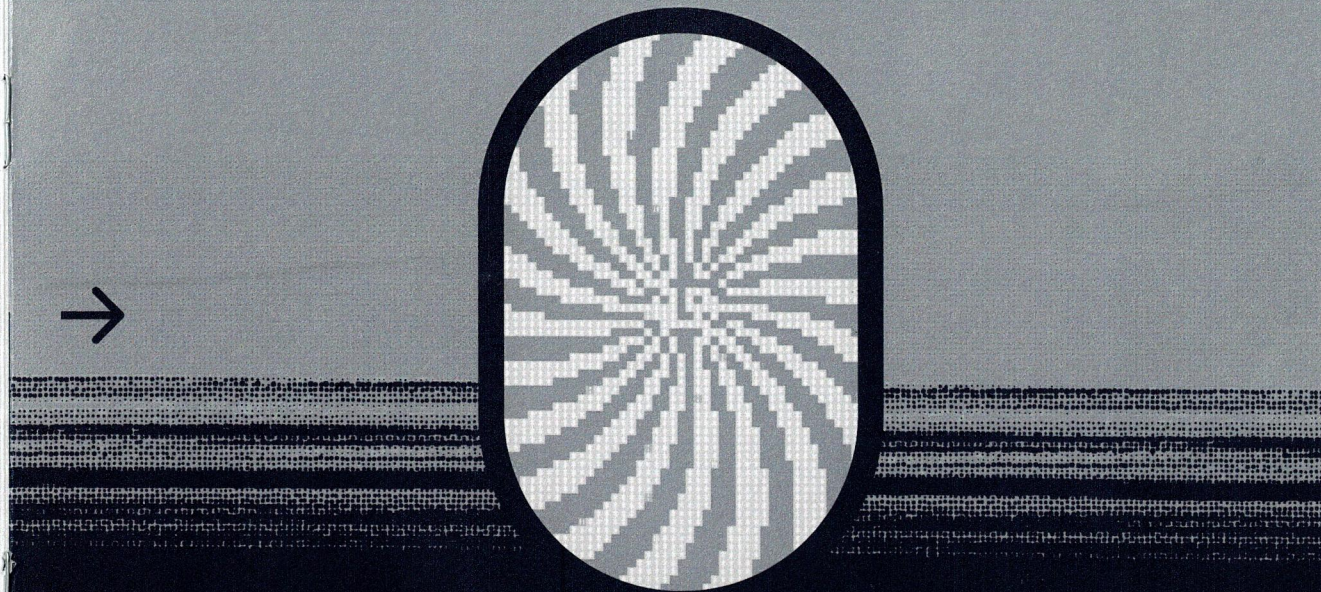

Air from surrounding areas with higher pressure pushes into the low-pressure area. Then that “new” air becomes warm and moist, and rises too.

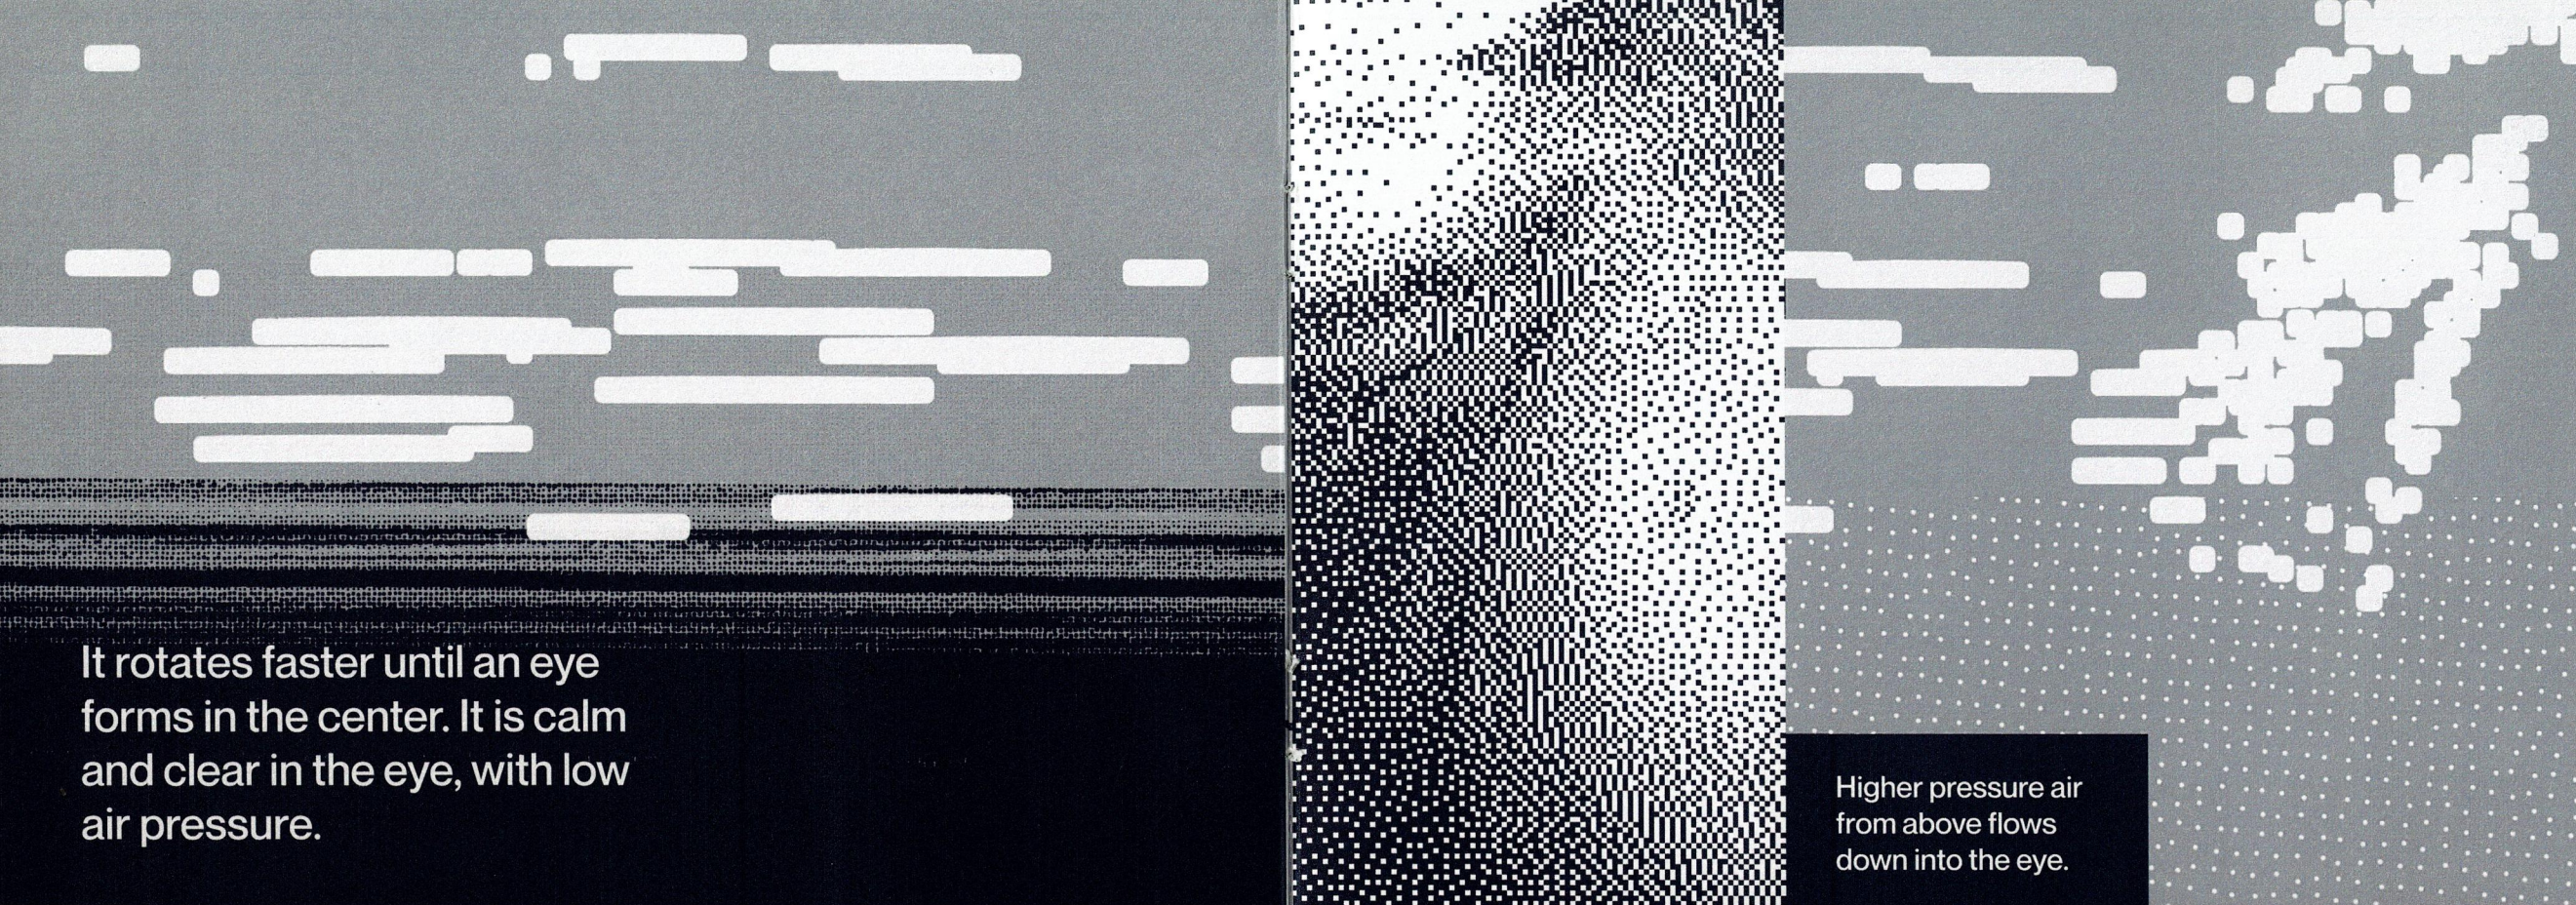

Water in the air forms clouds as it begins to cool.

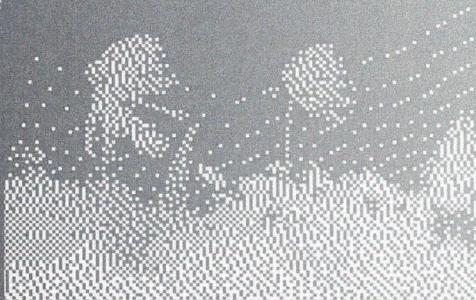

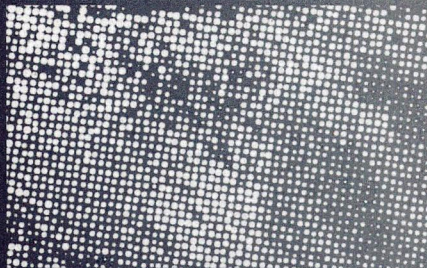

The system of clouds and wind spins and grows, fed by the ocean's heat and water evaporating from the surface.

It rotates faster until an eye forms in the center. It is calm and clear in the eye, with low air pressure.

Higher pressure air from above flows down into the eye.

Hurricanes weaken when they hit land because they are no longer being “fed” by the warm ocean waters.

They can often move far inland, dumping many inches of rain and causing wind damage, before dying out completely.
